CS - 501

B.E. V Semester

Examination, June 2016

Data Communication

Time: Three Hours

Maximum Marks: 70

- Note: i) Answer five questions. In each question part A, B, C is compulsory and D part has internal choice.
 - ii) All parts of each question are to be attempted at one place.
 - iii) All questions carry equal marks, out of which part A and B (Max.50 words) carry 2 marks, part C (Max.100 words) carry 3 marks, part D (Max.400 words) carry 7 marks.
 - iv) Except numericals, Derivation, Design and Drawing etc.
- What are the basic components of data communication?
 - b) Define Line and block codes.
 - What is the difference between serial and parallel transmission?
 - Explain the different types of digital signal encoding formats for signal 010011100011.

Or

Why the digital communication systems are more resistant to channel noise than analog systems.

- What are the nonlinear effects in FDMA?
 - b) Why is multiplexing needed in data communication systems?
 - c) Explain difference between packet and circuit switching.
 - Describe the basic concept of wavelength division multiplexing. List the advantages of WDM.

Discuss X.25 in detail.

www.rgpvonline.com

Differentiate between hub and bridge.

b) Define gateways.

- c) For n devices in a network, what is the number of cable links necessary for mesh, ring, bus and star networks.
- d) Define physical layer wiring standard of following: 10 Base 2,10 Base 5, 100 Base F and 1000 Base T.10.

Or

Explain network topologies with neat diagram.

- Name the advantage of optical fiber over coaxial cable.
 - b) Explain twisted-pair wire. Also explain its advantages.
 - Explain skip distance. c)
 - Define the following terms:
 - i) Transmission lines ii) Guided transmission lines
 - iii) Transverse waves
- iv) Longitudinal waves

Or

Explain the functioning of Digital Subscriber Line.

- Mention the types of error correcting methods.
 - b) What are the three types of redundancy checks used in data communications?
 - c) An 8-bit byte with binary value 10101111 is to be encoded using an even-parity hamming code. What is the binary value after encoding?
 - The message 101011000110 is protected by a CRC checksum that was generated with the polynomial x^6+x^4+x+1 . The checksum is in the tail (the right side) of the message.
 - i) How many bits is the checksum?
 - ii) If no transmission errors occurred, what would the original data be?
 - iii) Were there any transmission errors?

Hamming codes are a family of (n, k) block errorcorrecting code. Compute the hamming code for the given data bits "00111001".
